4 Block Diagram

A system block diagram of **CC1175** is shown Figure 4.1.

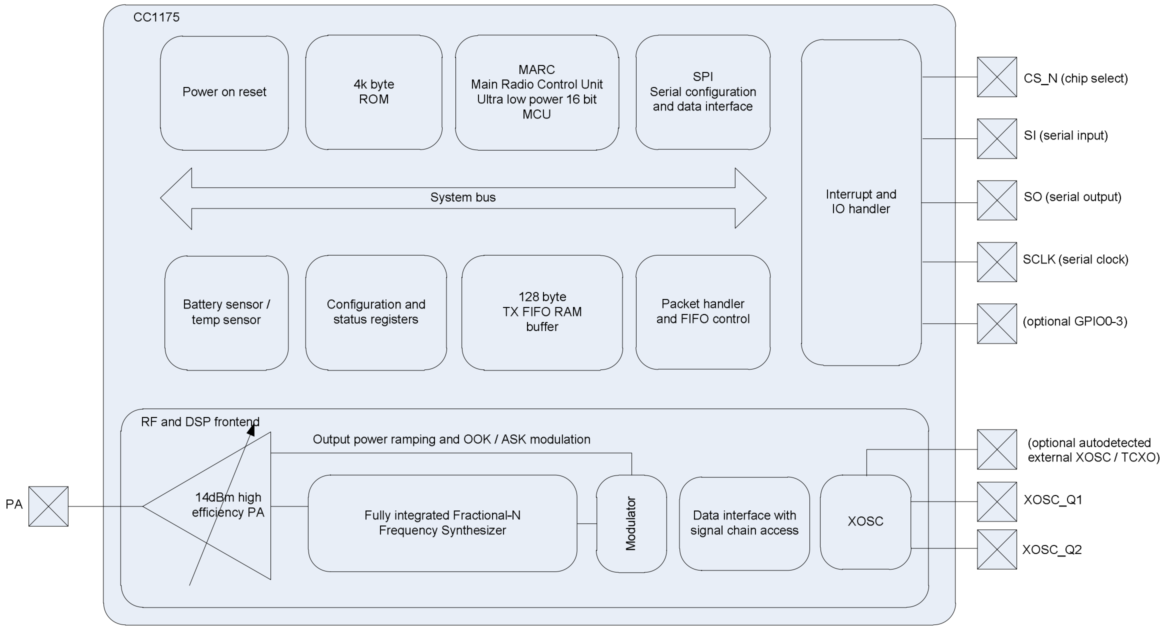

Figure 4.1 : System Block Diagram

4.1 Frequency Synthesizer

At the heart of **CC1175** there is a fully integrated, fractional-N, ultra high performance frequency synthesizer. The frequency synthesizer is designed for excellent phase noise performance. The system is designed to comply with the most stringent regulatory spectral masks at maximum transmit power.

Either a crystal can be connected to XOSC_Q1 and XOSC_Q2, or a TCXO can be connected to the external clock input. The oscillator generates the reference frequency for the synthesizer, as well as clocks for the digital part. If a TCXO is used, the **CC1175** will automatically turn the TCXO on and off when needed to support low power modes.

4.2 Transmitter

The **CC1175** transmitter is based on direct synthesis of the RF frequency (in-loop modulation). To achieve effective spectrum usage, **CC1175** has extensive data filtering and shaping in TX to support high throughput data communication in narrowband channels. The modulator also controls power ramping to remove issues such as spectral splattering when driving external high power RF amplifiers.

The modulator also controls the PA power level to support on/off keying (OOK) and amplitude shift keying (ASK).

4.3 Radio Control and User Interface

The **CC1175** digital control system is built around MARC (Main Radio Control) implemented using a high performance 16 bit ultra low power MCU. MARC handles power modes, radio sequencing and protocol timing.

A 4-wire SPI serial interface is used for configuration and data buffer access. The digital baseband includes support for channel configuration, packet handling, and data buffering. The host MCU can burst write data to TX FIFO and stay in power down until a the RF packet has been transmitted, greatly reducing the power consumption required from the host MCU.

The **CC1175** radio control and user interface is designed from the widespread sub-GHz **CC1101** transceiver to enable easy SW transition between the two platforms. The command strobes and the main radio states are the same on the two platforms.

For legacy formats **CC1175** also supports two serial modes. In synchronous serial mode **CC1175** provides the MCU with a bit clock for sampling input data. In transparent mode **CC1175** samples the input pin at a configurable rate.

4.4 Low Power / High Performance Mode

The **CC1175** is highly configurable, enabling trade-offs between power and performance to be made based on the needs of the application. This data sheet describes two modes - low power mode and high performance mode - which represent configurations where the device is optimized for either power or performance.

5 Typical Application Circuit

Very few external components are required for the operation of **CC1175**. A typical application circuit is shown below. Note that it does not show how the board layout should be done, the board layout will greatly influence the RF performance of **CC1175**.

This section is meant as an introduction only. Note that decoupling capacitors for power pins are not shown in the figure below.

After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).
